AEGIS

One-page team science statement

Contributors (reported by the project owner): Isaac handled the disease side; Micky provided coding help; the project owner led integration and user-facing workflow priorities. Contributor last names and the owner's final author name will be added by the team. No professional credentials or external interviews are claimed.

Team decision that changed: disease-side input helped the project incorporate CDC data, especially BEAM surveillance, and examine historical patterns. This is a project-owner-reported contribution. Separately, operator feedback about unhelpful chicken queries, unexplained map layers and texting while driving led to guided questions, task-based map explanations and parked-use driver controls.

The three core sources retain different roles: PulseNet-derived BEAM human aggregates provide regional context; FSIS selected poultry samples provide the retrospective target; NOAA observations provide an ambient index. NORS historical outbreaks and USDA Food Environment Atlas add two domains. No person, genome, lot, supplier or outbreak is causally linked by co-location.

Measured added-data result: the 171-sample Missouri holdout has core Brier 0.11246 versus baseline 0.11431. Added BEAM/NOAA effects remain uncertain; NORS Brier is 0.12449 in this cohort, with a constant holdout feature. Read the recorded paired intervals; no gain is assumed. USDA stays contextual because fictional recipients lack a verified county/needs cross-walk.

Next partner/data: a real refrigerated distributor and public-health/food-safety partner could supply deidentified lot/establishment/time traceability, result-publication timestamps, calibrated cargo histories and recipient receiving/demand data. These would improve availability and access analyses. Kiro was not used, as disclosed by the owner. Software checks do not establish prospective validity, team signoff or a timed human video. Full role/decision wording is in docs/team_science_statement.md and requires author review.
